Abstract

1 Overview

2 Theoretical Description

2.1 Non Local Means

Self similarities inside pictures have been studied for a long time. Efros and Leung used it for texture synthesis [1] and were followed by Buades, Coll and Morel for denoising purpose [2].

Considering a noisy picture \mathbf{y} of n pixels seen as a column vector in \mathbb{R}^n , \mathbf{y} is divided into n overlapping patches of equal size m. The i-th pixel of \mathbf{y} is noted $\mathbf{y}[i]$ and the patch centered in $\mathbf{y}[i]$ and of size m is noted \mathbf{y}_i . Then, when two different patches \mathbf{y}_i and \mathbf{y}_j have similar values, their denoised version should also be similar. Moreover, assuming that the noise follows a Gaussian distribution, averaging similar patches should destroy the noise information and thus denoise the patch. Thus the denoised pixel $\mathbf{x}[i]$ is obtained with a linear combination of the others pixel in the noisy picture \mathbf{y} weighted by the similarity of their corresponding patches:

$$\mathbf{x}[i] = \frac{1}{N} \sum_{j=1}^{n} G(\mathbf{y}_i - \mathbf{y}_j) \mathbf{y}[j]$$
 (1)

where N is the normalization factor and G a Gaussian that weights the patch similarities. Following this idea, Mairal et al. [5] divided the pictures into n overlapping patches in order to denoise through self-similarity methods.

2.2 Learned Sparse Coding

The second idea is to assume that the denoised patches can be approximated by a sparse linear combinations of elements from a basis set.

This basis set, that contains the denoised picture information, is called a dictionary $\mathbf{D} \in \mathbb{R}^{m \times k}$. The linear combination is represented by a vector $\boldsymbol{\alpha} \in \mathbb{R}^k$ called a code. The aim is to have a dictionary that is not redundant (independant columns), not too large $(k \ll n)$ but that contains the whole picture information.

The denoising problem consists then of finding one dictionary for the picture and one sparse code for each patch. Thus it can be reformulated into a minimization problem where we look for the optimal dictionary and codes that are the most similar to each noisy patches:

$$\min_{\mathbf{D}, \boldsymbol{\alpha}_i} \sum_{i=1}^n ||\boldsymbol{\alpha}_i||_p \text{ s.t. } \forall i \in [1, n], \quad ||\mathbf{y}_i - \mathbf{D}\boldsymbol{\alpha}_i||_2^2 \leqslant \epsilon$$
with $\mathbf{D} \in \mathbb{R}^{m \times k}$ and $\forall i \in [1, n], \quad \boldsymbol{\alpha}_i \in \mathbb{R}^k$

 $\mathbf{D}\alpha_i$ is the estimate of the i^{th} denoised patch which should be similar to the noisy patch and ϵ can be chosen according to the value of the estimated standard deviation of the noise.

Once the dictionary and the codes are learned, for each pixel, we have m estimations (from the m overlapping patches that contain it) and their averaging give us the denoised information of this pixel:

$$\forall i \in [1, n], \quad \mathbf{x}[i] = \frac{1}{m} \sum_{j=1}^{m} \mathbf{D} \boldsymbol{\alpha}_{\sigma(i,j)}$$
(3)

Where $\sigma(i,j)$ Marc: il faudrait changer σ pour une autre notation, pour ne pas confondre avec le bruit is the number of the patch that put pixel $\mathbf{x}[i]$ in j^{th} position.

Equation (2) is usually minimized with p=0 or 1. It becomes NP-hard to solve when p=0 but a greedy algorithm such as Orthogonal Matching Pursuit (ORMP) [7] can quickly give a good approximation. The problem is convex with p=1 and is efficiently solved with the Least Angle Regression (LARS) algorithm [3]. Experimental observations [8] have shown that the learning part is better with p=1 and the recomposition part with p=0.

2.2.1 Learning Dictionary

In this part, we consider that p = 1 in equation (2). The problems becomes convex and the equation is only solved in order to find the optimal dictionary **D** that could represent the denoised information of picture **y**.

The method consists in updating the dictionary iteratively with only a small distribution of T patches. However they are chosen so that they are independently and identically distributed in the picture.

First, the initial dictionnary is learned offline on the 10 000 images of the PASCAL VOC'07 database using the online dictionary learning procedure of [4]. This procedure is then used on the noisy picture **y** in order to improve the dictionary efficiency.

For each patch \mathbf{y}_i , the corresponding code is computed with the current dictionary kept constant and then the dictionary is updated with all the previous codes.

Thus, we minimize iteratively the two equations below:

- For $\mathbf{D} \in \mathbb{R}^{m \times k}$ and patch t, Marc: il faudrait rajouter fixed ou set, non? car au début j'ai cru que c'était une boucle for... $\boldsymbol{\alpha}^t = \operatorname{argmin}_{\boldsymbol{\alpha} \in \mathbb{R}^k} ||\boldsymbol{\alpha}||_1$ s.t. $||\mathbf{y}_t \mathbf{D}^{t-1} \boldsymbol{\alpha}||_2^2 \leq \lambda$
- For patches 1 to t and their codes $\boldsymbol{\alpha} \in \mathbb{R}^k$ Marc: il faudrait rajouter fixed ou set, non?, $\mathbf{D}^t = \underset{\mathbf{D} \in \mathbb{R}^{m \times k}}{\operatorname{argmin}}_{\mathbf{D} \in \mathbb{R}^{m \times k}} \frac{1}{t} \sum_{i=1}^{t} (\frac{1}{2} |\mathbf{y}_t^i \mathbf{D} \boldsymbol{\alpha}^i||_2^2 + \lambda ||\boldsymbol{\alpha}^i||_1)$

The first equation is solved with the LARS algorithm.

Yohann: TODO

The second equation can be re-written:

$$\mathbf{D}^{t} = \operatorname{argmin}_{\mathbf{D} \in \mathbb{R}^{m \times k}} \frac{1}{t} \left(\frac{1}{2} \operatorname{Tr}(\mathbf{D}^{T} \mathbf{D} B^{t}) - \operatorname{Tr}(D^{T} C^{t}) \right)$$
(4)

where B and C are incrementaly updated with:

- $B^t \leftarrow B^{t-1} + \alpha^t \alpha^{tT}$
- $C^t \leftarrow C^{t-1} + \mathbf{y}^t \boldsymbol{\alpha}^{tT}$

The dictionary update is thus computed through a block-coordinate descent with warmrestarts [9]. This is an iterative method that updates the columns of the dictionary needing only matrices B and C and no matrix inversion in opposite to other approaches as Newton method. Moreover, since the convex optimization problem (Equation (4)) admits separable constraints in the updated blocks (columns), convergence to a global optimum is guaranteed. However Mairal et al empirically found that a single iteration of the dictionary update was sufficient to achieve convergence.

2.2.2 Denoising

TODO: MARC:)

An Orthogonal Recursive Matching Pursuit (ORMP) gives an approximate solution of the (NP-complete) problem

$$\operatorname{argmin}_{\alpha_{ij}} ||\alpha_{ij}||_0 \text{ such that } ||\boldsymbol{R}_{ij}\boldsymbol{y} - \hat{\boldsymbol{D}}\alpha_{ij}||_2^2 \le \epsilon$$
 (5)

where $||\alpha_{ij}||_0$ refers to the l^0 norm of α_{ij} , i.e. the number of non-zero coefficients of α_{ij} . If it were perfect, this ORMP would find a patch with the sparsest representation in $\hat{\boldsymbol{D}}$ in which the distance to $\boldsymbol{R}_{ij}\boldsymbol{y}$ is less than ϵ . In fact the ORMP is not perfect: indeed, it only allows one to find a patch having one sparse (not necessarily the sparsest) representation in $\hat{\boldsymbol{D}}$ and which distance to $\boldsymbol{R}_{ij}\boldsymbol{y}$ is lower than ϵ .

For more explanations on this algorithm, the reader may refer to [11], in particular the section 2.1.1 Sparse Coding. Marc: il faut en mettre plus ou pas? J'ai rajouté la citation à KSVD dans la biblio.

2.3 Simultaneous Sparse Coding

The idea that developped Mairal et al. in this section is that similar patches should have similar decomposition upon the dictionary. Thus, they created a partition of the picture into n_C groups of similar patches called clusters. They then added a simultaneous condition which impose similar decompositions for patches of the same cluster and equation (2) became:

$$\min_{\mathbf{D}, \boldsymbol{\alpha}_{i,j}} \sum_{j=1}^{n_C} \sum_{i=1}^{n_j} \frac{||\boldsymbol{\alpha}_{i,j}||_q^p}{n_j} \text{ s.t. } \forall j \in [1, n_C], \quad \sum_{i=1}^{n_j} ||\mathbf{y}_i - \mathbf{D}\boldsymbol{\alpha}_{i,j}||_2^2 \leqslant \epsilon_j$$
with $\mathbf{D} \in \mathbb{R}^{m \times k}$ and $\forall i \in [1, n_j], \forall j \in [1, n_C], \quad \boldsymbol{\alpha}_{i,j} \in \mathbb{R}^k$

where n_j is the size of the j^{th} cluster and ϵ_j is chosen with respect to the noise inside it.

Equation (6) is usualy minimized with $(p,q)=(0,\infty)$ or (1,2). As for Equation (2), it becomes NP-hard to solve when $(p,q)=(0,\infty)$ and Simultaneous Orthogonal Recursive Matching Pursuit (SORMP) [10] gives a good approximation. The problem is convex when (p,q)=(1,2) and a slight modification of the LARS algorithm gives a solution. Once again, the convex problem is used for the learning part while the SORMP is used for the denoising part.

As for the non-simultaneous sparse coding, the denoised pixel is approximated by an average of the denoised versions of all the overlapping patches.

2.3.1 Simultanous Learning

Not seen in details. The algorithm used is the Simultaneous LARS which is similar to LARS but a "simultaneous" condition that uses cluster information.

Marc: on va rajouter des trucs là non?

2.3.2 Simultanous Denoising

Not seen in details. The algorithm used is the Simultaneous ORMP which is similar to ORMP but a "simultaneous" condition that uses cluster information.

Marc: on va rajouter des trucs là non ?

3 Notations

4 Algorithm Description

4.1 Algorithm Overview

The previous parts are used in order to perform a global denoising. First, a rough denoising is realized upon the whole picture. This way, a coherent dictionary is learned and similar patches can be easily regrouped. Then, the clustering is performed and the previous process is applied once more on each cluster indepently. However, the similarity between patches is also used, adding a simultaneous condition upon patches. The whole algorithm is summed up in Algorithm 1.

Algorithm 1: Online Dictionary Learning

Note that in practice N = 1 works well and the patchwise update for the dictionary is very costy and do not seem to increase the quality of the denoised picture.

The pseudo code is presented below with the same subsections as the theoretical part above. We implemented it in C++ and the link between the pseudo code and the C++ functions is precised each time.

4.2 Learned Sparse Coding

4.2.1 Learning Dictionary

• Main function of the dictionary learning part - trainL1:

It computes a distribution of iid patches with the function getRandList. It then iteratively minimizes equation (2) with either the dictionary **D** fixed or the codes α fixed. When the dictionary is fixed, the LARS is used in C++ function computeLars. When the codes are fixed, the C++ function called is updateDictionary.

Input: initial dictionary $\mathbf{D}^0 \in \mathbb{R}^{m \times k}$, number of iterations \mathbf{T} , regularization parameter λ

Output: learned dictionary D

Initialization : $\mathbf{A}^0 \in \mathbb{R}^{k \times k} \leftarrow 0$, $\mathbf{B}^0 \in \mathbb{R}^{m \times k} \leftarrow 0$

Compute i.i.d. sampling of **T** patches of the noisy picture \mathbf{Y}_T for $t = 1...\mathbf{T}$ do

$$\mathbf{y}_t = \mathbf{Y}_T[t]$$

Sparse coding: compute with LARS algorithm:

$$\alpha^t = \operatorname{argmin}_{\alpha \in \mathbb{R}^k} ||\alpha||_1 \text{ s.t. } ||\mathbf{y}_t - \mathbf{D}^{t-1}\alpha||_2^2 \le \lambda$$

$$\mathbf{A}^t \leftarrow \mathbf{A}^{t-1} + \boldsymbol{\alpha}^t \boldsymbol{\alpha}^{tT} \\ \mathbf{B}^t \leftarrow \mathbf{B}^{t-1} + \mathbf{y}_t^t \boldsymbol{\alpha}^{tT}$$

Update dictionary from \mathbf{D}^{t-1} to \mathbf{D}^t so that:

$$\mathbf{D}^{t} = \operatorname{argmin}_{\mathbf{D} \in \mathbb{R}^{m \times k}} \frac{1}{t} \sum_{i=1}^{t} (\frac{1}{2} |\mathbf{y}_{t}^{i} - \mathbf{D} \boldsymbol{\alpha}^{i}||_{2}^{2} + \lambda ||\boldsymbol{\alpha}^{i}||_{1})$$

 $\begin{array}{c} \mathbf{end} \\ \mathbf{return} \ \mathbf{D}^T \end{array}$

return D

Algorithm 2: trainL1

• Dictionary update - updateDictionary:

Block-coordinate descent with warmrestarts algorithm that minimizes Equation (4). TODO: se renseigner sur la methode? pk si A(j,j) = 0 ...

Algorithm 3: updateDictionary

• Least Angle Regression (LARS) - computeLars:

The LARS algorithm is very long and has been split up for better readibility.

(min⁺ is the minimum between strictly positive values only)

TODO: preiser la version + pk inversion bizarre des matrices

Input: Input dictionary $\mathbf{D} \in \mathbb{R}^{m \times k}$, noisy patch $\mathbf{y} \in \mathbb{R}^m$, constraint $\lambda \in \mathbb{R}$

Output : code $\alpha \in \mathbb{R}^k$

Initialization:

Initialize variables

for i = 1..k do

New atom:

Add a new atom in α if there is no downdating

Compute steps:

Compute the initial step (γ)

Compute the critical step that impose downdating (stepDownDate)

Compute the critical step that breaks the loop and ends the algorithm (stepMax)

Update code:

Compute the new code α and downdate or break if needed

end

return α

Algorithm 4: computeLars - Main

Compute Gram matrix:

$$\mathbf{G} \in \mathbb{R}^{k \times k} \leftarrow \mathbf{D}^T \mathbf{D}$$

Initialize patch norm and check if there is no trivial solution:

normPatch $\in \mathbb{R}^+ \leftarrow ||\mathbf{y}||_2^2$

if $normPatch < \lambda$ then

return 0

end

Initialize code and active index:

 $oldsymbol{lpha} \in \mathbb{R}^k \leftarrow oldsymbol{0}$

$$\mathcal{A} \in \llbracket 0, k \rrbracket^k \leftarrow \mathbf{0}$$

Compute most correlated element:

$$\hat{\mathbf{c}} \in \mathbb{R}^k \leftarrow \mathbf{D}^T \mathbf{y}$$

$$C \in \mathbb{R}^+ \leftarrow \max_{j=1..k}(|\hat{\mathbf{c}}[j]|)$$

currentInd
$$\leftarrow j$$
 s.t. $\hat{\mathbf{c}}[j] = C$

Add a new atom at first iteration:

 $newAtom \leftarrow True$

Algorithm 5: computeLars - Initialization

```
\mathcal{A}[i] \leftarrow \text{currentInd}
       G_A \in \mathbb{R}^{k \times i}, G_S \in \mathbb{R}^{i \times i}
       G_A[i^{th} \text{ column}] \leftarrow G[\text{currentInd}^{th} \text{ column}]

G_S[i^{th} \text{ line}] \leftarrow G_A[\text{currentInd}^{th} \text{ line}]
       symmetrize G_S: copy the lower part of G_S into its upper part
       UPDATE G_S^{-1}
end
                                                    Algorithm 6: computeLars - New atom
Initial step:
\mathbf{u} \in \mathbb{R}^i \leftarrow \hat{G}_S^{-1}(\operatorname{sgn}(\hat{\mathbf{c}}[\mathcal{A}[j]]))_{j \in [\![1,i]\!]}
C \leftarrow |\hat{\mathbf{c}}[\mathcal{A}[1]]| = \max_{j=1..k} (|\hat{\mathbf{c}}[j]|)
\gamma \in \mathbb{R}_{*}^{+} \leftarrow \min^{+} \left( \frac{C + \hat{\mathbf{c}}[j]}{1 + (G_{A}u)[j]}, \frac{C - \hat{\mathbf{c}}[j]}{1 - (G_{A}u)[j]} \right)_{j \text{ s.t. } \mathcal{A}[j] = 0}
currentInd = j s.t. \gamma = \frac{C \pm \hat{\mathbf{c}}[j]}{1 \pm (G_A u)[j]}
Downdate step:
ratio \in \mathbb{R}^i \leftarrow \left(-\frac{\alpha[\mathcal{A}[j]]}{u_j}\right)_{j \in [\![1,i]\!]}
stepDownDate \in \mathbb{R}^+_* \leftarrow min^+(ratio)
downDateInd \in [1, k] \leftarrow A[j] s.t. ratio[j] = stepDownDate
Breaking step:
a \in \mathbb{R} \leftarrow \sum_{j \in [1,i]} \operatorname{sgn}(\hat{\mathbf{c}}[\mathcal{A}[j]]) u[j]

b \in \mathbb{R} \leftarrow \sum_{j \in [1,i]} \hat{\mathbf{c}}[\mathcal{A}[j]] u[j]

c \in \mathbb{R} \leftarrow \operatorname{normPatch} - \lambda
\Delta \in \mathbb{R} \leftarrow b^2 - ac
stepMax \in \mathbb{R}^+ \leftarrow \min(\frac{b-\sqrt{\Delta}}{a}, C)

Algorithm 7: computeLars - Compute steps
\gamma \leftarrow \min(\gamma, \text{stepDownDate}, \text{stepMax})
for j = 1..i do
 | \boldsymbol{\alpha}[\mathcal{A}[j]] \leftarrow \boldsymbol{\alpha}[\mathcal{A}[j]] + \gamma \mathbf{u}[j]
end
\hat{\mathbf{c}} \leftarrow \hat{\mathbf{c}} - \gamma G_A u
normPatch \leftarrow normPatch + a\gamma^2 - 2b\gamma
if |\gamma| < 10^{-6} or \gamma = stepMax or normPatch < 10^{-6} or normPatch - \lambda < 10^{-6} then
 break
end
if \gamma = stepDownDate then
       DOWNDATE G_S^{-1} w.r.t downDateInd
       \mathcal{A}[\text{downDateInd}] \leftarrow 0
       \alpha[\text{downDateInd}] \leftarrow 0
       newAtom \leftarrow False
      i \leftarrow i - 1
end
else
       newAtom \leftarrow True
      i \leftarrow i + 1
end
                                                  Algorithm 8: computeLars - Update code
```

if newAtom then

```
Input: Gram matrix G_S \in \mathbb{R}^{i \times i}, and its former inverse to update G_S^{-1} \in \mathbb{R}^{i-1 \times i-1}
Output: updated G_S^{-1} \in \mathbb{R}^{i \times i}
if i = 1 then
 return \frac{1}{G_S}
end
u \leftarrow G_S^{-1}G_S[i^{th} \text{ line}]

\sigma \leftarrow \frac{1}{G_s(i,i) - u.G_S[i^{th} \text{ line}]} 

G_s^{-1}(i,i) \leftarrow \sigma 

G_s^{-1}[i^{th} \text{ line}] \leftarrow -\sigma u

return G_s^{-1} \leftarrow G_s^{-1} + \sigma u u^T
Algorithm 9: updateGram Marc: Algo correspondent, mais à valider.
Input: pseudo-Gram matrix G_A \in \mathbb{R}^{k \times i} Gram matrix G_S \in \mathbb{R}^{i \times i}, and its inverse G_S^{-1} \in \mathbb{R}^{i \times i},
criticalInd \in [1, k], current iteration i
Output: downdated matrices G_A \in \mathbb{R}^{k \times i-1}, G_S, G_S^{-1} \in \mathbb{R}^{i-1 \times i-1}
\sigma \leftarrow \frac{1}{G_S^{-1}(\text{criticalInd},\text{criticalInd})}
u \leftarrow G_S^{-1}[\text{criticalInd}^{th} \text{ line}] \text{ without its criticalInd}^{th} \text{ coefficient}
